

Project Name: TripSync

Type: Mobile application (React Native) with a JS/TS backend (currently FastAPI → migrating to Hono).

High-Level Description

TripSync is a **college-based ride-pooling and social interaction platform** that helps students travel together and connect within the campus community.

Core Features

1. Ride Pooling System

- Users create rides with:
 - Start point
 - Destination
 - Date & time
 - Price per seat
- Other students can join available rides.

2. User Accounts

- Students log in with phone/email.
- Basic profile: name, college, photo, verification status.

3. Chat & Interaction

- Riders and drivers can message each other.
- Real-time updates on ride status.

4. Safety & Verification

- Students from same college only.
- Optional ID verification later.

5. Backend Responsibilities

- Authentication (JWT or session tokens).
- Ride CRUD.
- User profile CRUD.
- Matching rides by location/time.
- Real-time messaging (likely using WebSockets or a service).
- Database (PostgreSQL or Cloudflare D1 → depending on design).
- Handles input validation, error cases, and permissions.

Migration Goal

- Convert **existing FastAPI backend** (Python) into **Hono (TypeScript)**.
- Maintain:
 - route structure
 - database logic
 - validation rules
 - request/response shapes
- Improve:
 - performance on Cloudflare
 - edge-friendly architecture
 - cleaner modular structure

Tech Requirements

- The new backend must run smoothly on:

- **Cloudflare Workers**
 - Cloudflare KV / D1 (depending on use cases)
- Keep TypeScript strict.
- Use Hono's:
 - routing
 - middleware
 - validation
 - error handling
- Use Drizzle ORM if database needed.

Output Style Desired from Copilot

- Clean, production-ready TS code.
- Modular structure.
- Reuse existing logic from FastAPI whenever possible.
- Avoid shortcuts or oversimplification.
- Explain changes when rewriting complex logic.
